## Abstract

Ladder operators for the simplest version of a rationally extended quantum harmonic oscillator (REQHO) are constructed by applying a Darboux transformation to the quantum harmonic oscillator system. It is shown that the physical spectrum of the REQHO carries a direct sum of a trivial and an infinite-dimensional irreducible representation of the polynomially deformed bosonized  $\mathfrak{osp}(1|2)$  superalgebra. In correspondence with this the ground state of the system is isolated from other physical states but can be reached by ladder operators via non-physical energy eigenstates, which belong to either an infinite chain of similar eigenstates or to the chains with generalized Jordan states. We show that the discrete chains of the states generated by ladder operators and associated with physical energy levels include six basic generalized Jordan states, in comparison with the two basic Jordan states entering in analogous discrete chains for the quantum harmonic oscillator.

## 1 Introduction

Darboux transformations, introduced originally as a method to solve linear differential equations and generalized subsequently for Darboux-Crum(-Krein-Adler) transformations [1, 2, 3, 4, 5], find many important applications in physics. For a long period of time they were used in quantum mechanics in factorization method for solving Schrödinger equation [6, 7, 8, 9]. Nowadays they are exploited intensively in the context of supersymmetry. These transformations lie in the heart of supersymmetric quantum mechanics [10, 11, 12, 13, 14]. They are particularly employed for the construction of new solvable and quasi-exactly solvable quantum mechanical systems. The Darboux transformations play a fundamental role in investigation of nonlinear equations in partial derivatives and partial difference equations, where they allow to relate different integrable systems and provide an effective method for the construction of nontrivial solutions for them [5, 15]. Periodic Darboux chains generate finite-gap systems [16] in an alternative way to the original algebro-geometric approach [17, 18]. Such chains generate also the quantum harmonic oscillator (QHO) system and Painlevé equations [16, 19, 20], which are intimately related with isomonodromic deformations of linear systems and integrability properties of nonlinear systems in partial derivatives. Recently, the isomonodromic deformations [21, 22] and Darboux transformations played a key role in the discovery and investigation of the properties of the new class of exceptional orthogonal polynomials [4, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33]. One of such a family corresponds to exceptional Hermite

polynomials, which can be obtained by applying Darboux and Darboux-Crum transformations to the QHO system. The quantum mechanical systems appearing in such a way are described by certain rational extensions of the harmonic potential.

A simplest rationally extended quantum harmonic oscillator (REQHO) [23, 24] can be obtained from the QHO system by applying to it Darboux transformation generated by the “Wick-rotated” second excitation of the ground-state. The resulting system is characterized by an infinite tower of equidistant bound states which are separated from the ground-state by a triple energy gap. As a consequence, the general solution of the evolution problem for REQHO, like for the quantum harmonic and isotonic oscillators, is periodic in time with a constant (not depending on energy) period [23, 34, 35]. For the discussion of different aspects of this quantum mechanical system see Refs. [4, 23, 24, 25, 31, 32, 33].

It is known that the spectrum of the QHO carries an infinite-dimensional irreducible representation of the bosonized  $\mathfrak{osp}(1|2)$  superalgebra which can be generated by means of the creation and annihilation operators identified as fermionic generators [36, 37]<sup>1</sup>. In this context there appears a rather natural question: what are the ladder operators in rationally extended quantum harmonic oscillator systems and what spectrum generating algebras do they produce? In this paper we answer these questions for the simplest case of the REQHO system by employing the properties of the Darboux transformations. A special role in the construction we obtain belongs to generalized Jordan states.

The paper is organized as follows. In the next section we review general properties of the Darboux transformations and related Jordan states. In Section 3 we discuss discrete flows generated by the ladder operators in the QHO system and recall the bosonized superconformal  $\mathfrak{osp}(1|2)$  structure appearing in it in the form of the spectrum generating superalgebra. In Section 4 we generate the simplest REQHO by applying Darboux transformation to the QHO. Then we construct ladder operators for REQHO by a Darboux-dressing of the creation and annihilation operators of the QHO system, consider discrete flows and discuss a polynomially deformed bosonized  $\mathfrak{osp}(1|2)$  structure in the REQHO that reflects in a coherent way peculiarities of its spectrum. Section 5 is devoted to the conclusion and outlook. In Appendix we describe the action of the ladder operators on non-physical eigenstates of the quantum harmonic oscillator which are closely related to its physical spectrum, and present the construction of the net of associated Jordan and generalized Jordan states.

## 2 Darboux transformations and Jordan states

Let  $\psi_*(x)$  be a solution of the stationary Schrödinger equation  $H\psi_* = E_*\psi_*$ . For the moment we consider this equation formally as an abstract second order differential equation in which  $H = -\frac{d^2}{dx^2} + V(x)$  is a Hamiltonian operator with a real nonsingular on  $\mathbb{R}$  potential  $V(x)$ . A real constant  $E_*$  is treated here as an eigenvalue without preoccupying the questions of boundary conditions and normalizability for  $\psi_*(x)$ . Consequently, we do not distinguish functions  $\psi(x)$  and  $C\psi(x)$ , where  $C \in \mathbb{C}$ ,  $C \neq 0$ , and assume that modulo such a multiplicative factor  $\psi(x)$  is chosen to be a real-valued function. A linearly independent solution for the same eigenvalue  $E_*$  can be taken in the form

$$\widetilde{\psi}_*(x) = \psi_*(x) \int^x \frac{d\xi}{\psi_*^2(\xi)}. \quad (2.1)$$

Due to integration with an indefinite lower limit, function  $\widetilde{\psi}_*(x)$  is supposed to be defined up to an additive term proportional to  $\psi_*(x)$ . Assume now that  $E_*$  is chosen so that function  $\psi_*(x)$  is

---

<sup>1</sup>For some recent investigations on superconformal quantum mechanical symmetry and its applications see [38, 39, 40, 41, 42].

nodeless,  $\psi_*(x) \neq 0$ , and introduce the first-order differential operators

$$A_{\psi_*} = \psi_* \frac{d}{dx} \frac{1}{\psi_*} = \frac{d}{dx} - \mathcal{W}(x), \quad \mathcal{W}(x) = \frac{\psi'_*}{\psi_*}, \quad (2.2)$$

and  $A_{\psi_*}^\dagger = -\frac{d}{dx} - \mathcal{W}(x)$ , where prime denotes derivative in  $x$ . Note that as  $A_{\psi_*}$  and  $A_{\psi_*}^\dagger$  are first-order differential operators, their kernels are one-dimensional,

$$\ker A_{\psi_*} = \psi_*, \quad \ker A_{\psi_*}^\dagger = \frac{1}{\psi_*}. \quad (2.3)$$

These operators provide a factorization of the shifted for the constant  $E_*$  Hamiltonian,  $H - E_* = A_{\psi_*}^\dagger A_{\psi_*}$ . Potential  $V(x)$  and superpotential  $\mathcal{W}(x)$  are connected by a relation  $V(x) - E_* = \mathcal{W}^2 + \mathcal{W}'$ . The product with the permuted first-order operators,  $A_{\psi_*} A_{\psi_*}^\dagger = \check{H} - E_*$ , defines the associated partner system described by the Hamiltonian  $\check{H} = -\frac{d^2}{dx^2} + \check{V}(x)$  with  $\check{V}(x) - E_* = \mathcal{W}^2 - \mathcal{W}'$ . From the alternative factorization relations it follows immediately that the first-order operators  $A_{\psi_*}$  and  $A_{\psi_*}^\dagger$  intertwine quantum Hamiltonians  $H$  and  $\check{H}$ ,

$$A_{\psi_*} H = \check{H} A_{\psi_*}, \quad A_{\psi_*}^\dagger \check{H} = H A_{\psi_*}^\dagger. \quad (2.4)$$

If  $\psi_E$  is a physical (normalizable) or non-physical (non-normalizable) solution of the Schrödinger equation  $H\psi_E = E\psi_E$  for some eigenvalue  $E \neq E_*$ , then as a consequence of (2.4),  $A_{\psi_*}\psi_E$  will be an eigenstate of  $\check{H}$  of the same, physical or non-physical, nature for the same eigenvalue  $E$ :  $\check{H}(A_{\psi_*}\psi_E) = E(A_{\psi_*}\psi_E)$ . Particularly, for the linear independent solution  $\widetilde{\psi}_E$  constructed from  $\psi_E$  according to the rule (2.1),  $\widetilde{\psi}_E = \psi_E(x) \int^x d\xi / \psi_E^2(\xi)$ , we have  $\check{H}(A_{\psi_*}\widetilde{\psi}_E) = E(A_{\psi_*}\widetilde{\psi}_E)$ . On the other hand, for  $E = E_*$  and  $\psi_E = \widetilde{\psi}_*$  we find that

$$A_{\psi_*}\widetilde{\psi}_* = \frac{1}{\psi_*}. \quad (2.5)$$

The function  $\frac{1}{\psi_*}$  is the kernel of the operator  $A_{\psi_*}^\dagger$ , and therefore is an eigenstate of  $\check{H}$ ,  $(\check{H} - E_*)\frac{1}{\psi_*} = 0$ . Analogously, if  $\check{\psi}_E$  is an eigenfunction of  $\check{H}$  of eigenvalue  $E \neq E_*$ , then  $A_{\psi_*}^\dagger \check{\psi}_E$  is an eigenstate of  $H$  of the same eigenvalue,  $H(A_{\psi_*}^\dagger \check{\psi}_E) = E(A_{\psi_*}^\dagger \check{\psi}_E)$ . For  $E = E_*$  the application of  $A_{\psi_*}^\dagger$  to a linearly independent from  $\frac{1}{\psi_*}$  eigenfunction  $\widetilde{\left(\frac{1}{\psi_*}\right)}$  of  $\check{H}$  maps it into the kernel of  $A_{\psi_*}$ ,

$$A_{\psi_*}^\dagger \widetilde{\left(\frac{1}{\psi_*}\right)} = \psi_*, \quad (2.6)$$

that is the eigenstate of  $H$ .

The described structure of the Darboux transformations reveals an essential difference between the cases  $E \neq E_*$  and  $E = E_*$ . The action of the Darboux transformation generators on the eigenstates with  $E \neq E_*$  is of the two-cyclic nature in the following sense: if  $\psi$  is such that  $H\psi = E\psi$ , then  $A_{\psi_*}$  maps this state into an eigenstate of  $\check{H}$ ,  $A_{\psi_*}\psi = \check{\psi}$ ,  $\check{H}\check{\psi} = E\check{\psi}$ , while application of  $A_{\psi_*}^\dagger$  to  $\check{\psi}$  reproduces (up to a multiplicative factor) the initial state  $\psi$ . At the same time, for  $E = E_*$  we have  $A_{\psi_*}\widetilde{\psi}_* = \frac{1}{\psi_*}$ ,  $A_{\psi_*}^\dagger \frac{1}{\psi_*} = 0$  and  $A_{\psi_*}^\dagger \widetilde{\left(\frac{1}{\psi_*}\right)} = \psi_*$ ,  $A_{\psi_*}\psi_* = 0$ , and no analogous cyclic structure does appear. In this case the functions

$$\Omega_2(x) = \psi_*(x) \int^x \frac{1}{\psi_*(\xi)} \widetilde{\left(\frac{1}{\psi_*}\right)}(\xi) d\xi, \quad \check{\Omega}_2(x) = \frac{1}{\psi_*(x)} \int^x \psi_*(\xi) \widetilde{\psi}_*(\xi) d\xi \quad (2.7)$$

are the pre-images of  $\widetilde{\left(\frac{1}{\psi_*}\right)}$  and  $\widetilde{\psi_*}$ ,

$$A_{\psi_*}\Omega_2 = \widetilde{\left(\frac{1}{\psi_*}\right)} \equiv \check{\Omega}_1, \quad A_{\psi_*}^\dagger \check{\Omega}_2 = \widetilde{\psi_*} \equiv \Omega_1. \quad (2.8)$$

Similarly to the eigenstates of the form (2.1), functions  $\Omega_2(x)$  and  $\check{\Omega}_2(x)$  are defined modulo additive terms  $\psi_*(x)$  and  $\frac{1}{\psi_*(x)}$ , respectively. Wave functions (2.7) are not, however, formal eigenfunctions of  $H$  and  $\check{H}$ , but as a consequence of (2.8) they obey the relations  $A_{\psi_*}A_{\psi_*}^\dagger A_{\psi_*}\Omega_2 = 0$  and  $A_{\psi_*}^\dagger A_{\psi_*}A_{\psi_*}^\dagger \check{\Omega}_2 = 0$ . Therefore,

$$(H - E_*)^2 \Omega_2 = 0, \quad (\check{H} - E_*)^2 \check{\Omega}_2 = 0, \quad (2.9)$$

and we conclude that  $\Omega_2$  and  $\check{\Omega}_2$  are generalized eigenstates of  $H$  and  $\check{H}$  of rank 2 corresponding to the same eigenvalue  $E = E_*$ . Having in mind a generalization of relations of the form (2.9) which appear in the following, see particularly Eq. (4.16) below, we refer to  $\Omega_2$  and  $\check{\Omega}_2$  as Jordan states of order 2 [43, 44]. The states (2.7) can be generalized further by defining

$$\Omega_n(x) = \psi_*(x) \int^x \frac{1}{\psi_*(\xi)} \check{\Omega}_{n-1}(\xi) d\xi, \quad \check{\Omega}_n(x) = \frac{1}{\psi_*(x)} \int^x \psi_*(\xi) \Omega_{n-1}(\xi) d\xi, \quad (2.10)$$

where  $n = 2, 3, \dots$ . These states obey the relations  $A_{\psi_*}\Omega_n = \check{\Omega}_{n-1}$ ,  $A_{\psi_*}^\dagger \check{\Omega}_n = \Omega_{n-1}$ . Consequently we find that  $\Omega_n$  and  $\check{\Omega}_n$  are annihilated by differential operators of order  $n+1$  constructed in terms of  $A_{\psi_*}$  and  $A_{\psi_*}^\dagger$ . Namely, for even  $n = 2k$  we have  $A_{\psi_*}(A_{\psi_*}^\dagger A_{\psi_*})^k \Omega_{2k} = 0$ ,  $A_{\psi_*}^\dagger (A_{\psi_*} A_{\psi_*}^\dagger)^k \check{\Omega}_{2k} = 0$ , while for odd  $n = 2k - 1$  we obtain  $(A_{\psi_*}^\dagger A_{\psi_*})^k \Omega_{2k-1} = 0$  and  $(A_{\psi_*} A_{\psi_*}^\dagger)^k \check{\Omega}_{2k-1} = 0$ ,  $k = 1, \dots$ . In both cases of the even and odd values of  $n$  we have  $(H - E_*)^{n+1} \Omega_{2n} = 0$ ,  $(\check{H} - E_*)^{n+1} \check{\Omega}_{2n} = 0$ ,  $n = 1, 2, \dots$ , and  $(H - E_*)^{n+1} \Omega_{2n+1} = 0$ ,  $(\check{H} - E_*)^{n+1} \check{\Omega}_{2n+1} = 0$ ,  $n = 0, 1, \dots$ . Thus,  $\Omega_k$  and  $\check{\Omega}_k$  with  $k = 2n, 2n + 1$  are Jordan states of order  $n + 1$ . The described properties are illustrated by Figure 1.

Figure 1: Action of the Darboux transformation generators.

### 3 Discrete flows in harmonic oscillator system and the $\mathfrak{osp}(1|2)$

Let us consider now the QHO system with  $V(x) = x^2$ . Its physical bound eigenstates with eigenvalues  $E_n = 2n + 1$  are described by normalizable wave functions  $\psi_n(x) = H_n(x)e^{-x^2/2}$ ,  $n = 0, 1, \dots$ ,

where  $H_n(x)$  are the Hermite polynomials. The change  $x \rightarrow ix$  transforms Hamiltonian of the QHO

$$H = -\frac{d^2}{dx^2} + x^2 \quad (3.1)$$

into  $-H$ , from where it follows that the wave functions  $\psi_n^-(x) = \mathcal{H}_n(x)e^{x^2/2}$  with  $\mathcal{H}_n(x) \equiv H_n(ix)$  correspond to non-physical (i.e. non-normalizable) eigenstates of  $H$  with eigenvalues  $E_n^- = -(2n+1)$ . The corresponding functions  $\widetilde{\psi}_n$  and  $\widetilde{\psi}_n^-$  are non-physical (non-normalizable) eigenfunctions of  $H$  of eigenvalues  $E_n = 2n+1$  and  $E_n = -(2n+1)$ ,  $n = 0, 1, \dots$ , respectively. They will play important role in the structure and properties of the REQHO system [4, 23, 24, 25, 31, 32, 33].

The well known peculiarity of the QHO system in the context of the Darboux transformations is that the choice of  $E_* = 1$ ,  $\psi_* = \psi_0 = e^{-x^2/2}$  gives  $\mathcal{W} = -x$ , and as the factorizing operators  $A_{\psi_*}$  and  $A_{\psi_*}^\dagger$  we obtain the usual, up to a multiplicative factor  $\sqrt{2}$ , creation and annihilation operators,

$$a^- = \frac{d}{dx} + x, \quad a^+ = (a^-)^\dagger = -\frac{d}{dx} + x, \quad [a^-, a^+] = 2. \quad (3.2)$$

In this case if  $N = a^+ a^-$  denotes the number operator for the QHO (with the spectrum  $2n$ ,  $n = 0, 1, \dots$ , corresponding to a normalization chosen in (3.2)) we have

$$[N, a^\pm] = \pm 2 a^\pm, \quad H = N + 1. \quad (3.3)$$

As a result, the Darboux-partner system for the QHO turns out to be  $\check{H} = H + 2$ , which is the same quantum harmonic oscillator but just with the spectrum of physical states shifted in  $+2$ . Since  $\psi_0^- = 1/\psi_0$ , another choice  $E_* = -1$ ,  $\psi_* = \psi_0^-$  changes the role of the Darboux-generating operators,  $A_{\psi_*} = a^+$ ,  $A_{\psi_*}^\dagger = a^-$ , and the partner system  $\check{H} = H - 2$  in this second case is again the quantum harmonic oscillator but with the physical spectrum shifted in  $-2$ . The action of the ladder operators on physical and associated non-physical eigenstates of the QHO and on the related Jordan and generalized Jordan states is described in Appendix. The corresponding discrete flows generated by  $a^-$  and  $a^+$  are depicted in Figure 2.

Figure 2: Discrete flows of the ladder operators of the QHO. Operator  $a^-$  acts left and up, and  $a^+$  acts right and up.

In general, because of the two-cyclic structure associated with the Darboux transformations, there appears a supersymmetry in the extended system composed from  $H$  and  $\check{H}$ . Since for the

QHO with its equidistant spectrum the partner generated by the Darboux transformation based on the eigenfunction  $\psi_* = \psi_0$  (or on  $\psi_* = \psi_0^- = 1/\psi_0$ ) is the same system but just with the spectrum shifted exactly in one energy step  $\Delta E = +2$  (or,  $\Delta E = -2$ ), the Darboux transformation generators responsible for supersymmetric structure transmute into the ladder operators for the single harmonic oscillator system. Coherently with this, instead of a usual quantum mechanical supersymmetry of the composed system, single quantum harmonic oscillator itself is characterized by the *bosonized* superconformal  $\mathfrak{osp}(1|2)$  structure. The  $\mathfrak{osp}(1|2)$  Lie superalgebra is generated here by the set of operators

$$\mathcal{L}_\pm = \frac{1}{4}a^\pm, \quad J_0 = \frac{1}{8}\{a^+, a^-\} = \frac{1}{4}H, \quad J_\pm = \frac{1}{4}(a^\pm)^2, \quad (3.4)$$

with nontrivial (anti)commutation relations

$$\{\mathcal{L}_+, \mathcal{L}_-\} = \frac{1}{2}J_0, \quad \{\mathcal{L}_+, \mathcal{L}_+\} = \frac{1}{2}J_+, \quad \{\mathcal{L}_-, \mathcal{L}_-\} = \frac{1}{2}J_-, \quad (3.5)$$

$$[J_0, \mathcal{L}_\pm] = \pm \frac{1}{2}\mathcal{L}_\pm, \quad [J_+, \mathcal{L}_-] = -\mathcal{L}_+, \quad [J_-, \mathcal{L}_+] = \mathcal{L}_-, \quad (3.6)$$

$$[J_0, J_\pm] = \pm J_\pm, \quad [J_+, J_-] = -2J_0. \quad (3.7)$$

For this superalgebra a reflection operator  $\mathcal{R} = (-1)^{N/2} = e^{i\pi N/2}$  plays a role of a  $\mathbb{Z}_2$ -grading operator, i.e.

$$\mathcal{R}^2 = 1, \quad \{\mathcal{R}, \mathcal{L}_\pm\} = 0, \quad [\mathcal{R}, J_0] = [\mathcal{R}, J_\pm] = 0. \quad (3.8)$$

The operator

$$\mathcal{C}_{\mathfrak{osp}(1|2)} = -J_0^2 + \frac{1}{2}(J_+J_- + J_-J_+) + 2(\mathcal{L}_+\mathcal{L}_- - \mathcal{L}_-\mathcal{L}_+) \quad (3.9)$$

is the quadratic Casimir of the  $\mathfrak{osp}(1|2)$ .

This corresponds to the well known spectrum-generating superalgebra of the QHO [36, 37], on the physical eigenstates  $\psi_n(x)$  of which the infinite-dimensional irreducible representation of the  $\mathfrak{osp}(1|2)$  with  $\mathcal{C}_{\mathfrak{osp}(1|2)} = -\frac{1}{16}$  is realized. The generators of the  $\mathfrak{so}(2,1)$  Lie subalgebra (3.7) act irreducibly on the eigensubspaces of  $\mathcal{R}$  spanned by the states  $\psi_n(x)$  with even,  $n = 2n_+$ , and odd,  $n = 2n_- + 1$ ,  $n_\pm = 0, 1, \dots$ , values of  $n$ , where the operator  $J_0$  takes eigenvalues  $n_+ + \frac{1}{4}$  and  $n_- + \frac{3}{4}$ , respectively. On both these subspaces the  $\mathfrak{so}(2,1)$  Casimir operator  $\mathcal{C}_{\mathfrak{so}(2,1)} = -J_0^2 + \frac{1}{2}(J_+J_- + J_-J_+)$  takes the same value  $\mathcal{C}_{\mathfrak{so}(2,1)} = \frac{3}{16}$ .

In conclusion of this section we note that a structure with a hidden bosonized supersymmetry [45, 46] also appears in periodic finite-gap and reflectionless quantum mechanical systems [47]. There, however, hidden supersymmetry has a different origin associated with a presence of a non-trivial Lax-Novikov integral in the quantum mechanical systems related to finite-gap and soliton solutions of the Korteweg-de Vries equation.

## 4 Discrete flows in the REQHO and deformed superconformal $\mathfrak{osp}(1|2)$ structure

Take now a non-physical eigenstate  $\psi_2^-(x) = (2x^2 + 1)e^{x^2/2}$  of the harmonic oscillator as the function  $\psi_*$  to generate Darboux transformation. This is a nodeless function, and the associated Darboux-transformed system will be given by a non-singular on  $\mathbb{R}$  potential. For the sake of simplicity we

denote by  $A^-$  the corresponding first order operator (2.2), in which the superpotential

$$\mathcal{W}(x) = \frac{d}{dx} (\ln \psi_2^-) = x + \frac{4x}{2x^2 + 1} = x + \frac{1}{x + \frac{i}{\sqrt{2}}} + \frac{1}{x - \frac{i}{\sqrt{2}}} \quad (4.1)$$

has simple poles at  $\infty$  and  $\pm \frac{i}{\sqrt{2}}$ . By construction,  $A^- \psi_2^- = 0$ , and  $A^+ \left( \frac{1}{\psi_2^-} \right) = 0$ , where  $A^+ = (A^-)^\dagger$ . A simple computation gives

$$A^+ A^- = -\frac{d^2}{dx^2} + x^2 + 5 = N + 6 \equiv H_O, \quad (4.2)$$

$$A^- A^+ = -\frac{d^2}{dx^2} + x^2 + 3 + 8 \frac{2x^2 - 1}{(2x^2 + 1)^2} \equiv \check{H}_O, \quad (4.3)$$

where  $N$  is the number operator for the QHO,  $N = a^+ a^-$ . Here  $H_O$  represents the QHO Hamiltonian shifted by an additive constant 5. Hamiltonian operator  $\check{H}_O$  describes the REQHO system with the physical bound states  $\Psi_0 = \frac{1}{\psi_2^-} = A^- \widetilde{\psi_2^-}$  and  $\Psi_{n+1} = A^- \psi_n$  of energies  $E_0 = 0$  and  $E_{n+1} = 6 + 2n$ ,  $n = 0, 1, \dots$ , constructed from the corresponding QHO states.

Let us introduce the third order differential operators

$$\mathcal{A}^- = A^- a^- A^+, \quad \mathcal{A}^+ = (\mathcal{A}^-)^\dagger = A^- a^+ A^+. \quad (4.4)$$

These are the Darboux-dressed ladder operators of the QHO. The operator  $A^+$  maps a physical or non-physical eigenstate of  $\check{H}_O$  into an eigenstate (of the same nature) of the QHO, to which  $a^-$  or  $a^+$  is then applied, and the obtained in this way eigenstate of  $H_O$  is mapped by  $A^-$  into another eigenstate of  $\check{H}_O$ . Operators (4.4) satisfy the following commutation relations with the REQHO Hamiltonian,

$$[\check{H}, \mathcal{A}^\pm] = \pm 2\mathcal{A}^\pm, \quad (4.5)$$

for which from now on we use a simplified notation  $\check{H}$ . To find (4.5) we used the intertwining relations  $A^+ \check{H} = H_O A^+$ ,  $A^- H_O = \check{H} A^-$  as well as Eq. (3.3). Relation (4.5) is generalized further for

$$[\check{H}, \mathcal{A}^{\pm n}] = \pm 2n \mathcal{A}^{\pm n}, \quad n = 1, 2, \dots, \quad (4.6)$$

and  $f(\check{H})\mathcal{A}^\pm = \mathcal{A}^\pm f(\check{H} \pm 2)$  for an arbitrary polynomial function  $f(\check{H})$ .

The operators  $\mathcal{A}^+$  and  $\mathcal{A}^-$  transform eigenstates of  $\check{H}$ , which are not from their kernels, into eigenstates of  $\check{H}$  with the increased and decreased in two energy values. In this aspect they act analogously to the ladder operators  $a^+$  and  $a^-$  in the QHO system. There are, however, essential differences. These third order differential operators satisfy relations

$$\mathcal{A}^+ \mathcal{A}^- = \check{H}(\check{H} - 2)(\check{H} - 6) \equiv \Phi(\check{H}), \quad \mathcal{A}^- \mathcal{A}^+ = \check{H}(\check{H} + 2)(\check{H} - 4) = \Phi(\check{H} + 2), \quad (4.7)$$

which follow from (4.2), (4.3), (3.3) and intertwining properties of  $A^\pm$ , and include the degree three polynomial  $\Phi(\lambda) = \lambda(\lambda - 2)(\lambda - 6)$ . From (4.7) and (4.6) we also obtain the relations which will be used in what follows:

$$\mathcal{A}^{+2} \mathcal{A}^- = \Phi(\check{H} - 2) \mathcal{A}^+, \quad \mathcal{A}^- \mathcal{A}^{+2} = \Phi(\check{H} + 2) \mathcal{A}^+, \quad (4.8)$$

$$\mathcal{A}^{-2} \mathcal{A}^+ = \Phi(\check{H} + 4) \mathcal{A}^-, \quad \mathcal{A}^+ \mathcal{A}^{-2} = \Phi(\check{H}) \mathcal{A}^-, \quad (4.9)$$

$$\mathcal{A}^{+2}\mathcal{A}^{-2} = \Phi(\check{H})\Phi(\check{H} - 2), \quad \mathcal{A}^{-2}\mathcal{A}^{+2} = \Phi(\check{H} + 2)\Phi(\check{H} + 4). \quad (4.10)$$

Both third order polynomials  $\Phi(\check{H})$  and  $\Phi(\check{H} + 2)$  in (4.7) include a factor  $\check{H}$ . This reflects the essential peculiarity of the REQHO system: its ground-state  $\Psi_0$  of zero energy is annihilated by both operators  $\mathcal{A}^-$  and  $\mathcal{A}^+$ ,

$$\mathcal{A}^-\Psi_0 = \mathcal{A}^+\Psi_0 = 0, \quad (4.11)$$

because  $\Psi_0 = \frac{1}{\psi_2}$  is the kernel of  $A^+$ .

Consider now other properties of the lowering ladder operator  $\mathcal{A}^-$ . It also annihilates the first excited physical state  $\Psi_1(x) = A^-\psi_0(x)$ ,  $\mathcal{A}^-\Psi_1 = 0$  due to sequential action of the operators  $A^+$  and then  $a^-$ . Moreover, it annihilates a non-physical eigenstate  $A^-\psi_1^-$  of  $\check{H}$  by means of transforming it by the second order operator  $a^-A^+$  into the kernel of  $A^-$ . As the kernel of the third-order differential operator  $\mathcal{A}^-$  is three-dimensional, it is spanned by the three eigenstates of  $\check{H}$ ,

$$\ker \mathcal{A}^- = \text{span} \{ \Psi_0, A^-\psi_1^-, \Psi_1 \}, \quad (4.12)$$

whose eigenvalues  $E = 0, 2, 6$  correspond to zeros of the third degree polynomial  $\Phi(\check{H})$  in the first equality in (4.7). The operator  $\mathcal{A}^-$  acts as a lowering ladder operator, and it is also interesting to look for kernels of powers  $(\mathcal{A}^-)^n$  with  $n = 2, 3, \dots$ . *A priori* it is clear that due to the presence of another physical state in the kernel of  $\mathcal{A}^-$ , which is the first excited state  $\Psi_1$  in the spectrum of  $\check{H}$ , and of the non-physical state  $A^-\psi_1^-$  with eigenvalue  $E = 2$  located between the energies  $E = 0$  and  $E = 6$  of the physical zero modes of  $\mathcal{A}^-$ , some additional peculiarities have to appear in comparison with the case of the QHO. Note first that (4.6) implies that  $\ker (\mathcal{A}^-)^2$  must be invariant under the action of  $\check{H}$ . On the other hand, we remark that  $\ker \mathcal{A}^- \subset \ker (\mathcal{A}^-)^2$ . Moreover,  $\psi \in \ker (\mathcal{A}^-)^2$  if and only if  $\mathcal{A}^-(\psi) \in \ker \mathcal{A}^-$ , and therefore  $\ker (\mathcal{A}^-)^2$  is generated by  $\ker \mathcal{A}^-$  and the pre-images under  $\mathcal{A}^-$  of  $\Psi_0$ ,  $A^-\psi_1^-$  and  $\Psi_1$ , i.e. one finds that

$$\ker (\mathcal{A}^-)^2 = \text{span} \{ \ker \mathcal{A}^-, A^-\widetilde{\psi_1^-}, A^-\psi_0^-, \Psi_2 \}. \quad (4.13)$$

Here  $\widetilde{\Psi_2} = A^-\psi_1$  is a physical eigenstate at the next energy level  $E = 8$ , and two other states  $A^-\widetilde{\psi_1^-}$  and  $A^-\psi_0^-$  are non-physical eigenstates of  $\check{H}$  of energies  $E = 2$  and  $E = 4$ . Under the action of  $\mathcal{A}^-$  the states  $A^-\widetilde{\psi_1^-}$ ,  $A^-\psi_0^-$  and  $\widetilde{\Psi_2}$  are transformed into the states  $\Psi_0$ ,  $A^-\psi_1^-$  and  $\Psi_1$  from the kernel (4.12). One can proceed in this way and identify the action of the decreasing operator on all the physical eigenstates of the system and on the associated non-physical eigenstates of the special form  $\widetilde{\Psi_0}$ ,  $A^-\widetilde{\psi_n}$ ,  $n = 0, 1, \dots$ , and  $A^-\widetilde{\psi_n^-}$ ,  $A^-\widetilde{\psi_n^-}$ ,  $n = 0, 1, 3, 4, 5, \dots$ . This action is depicted on Figure 3. The figure also shows that the pre-images of all the indicated physical and non-physical eigenstates of  $\check{H}$  with eigenvalues  $E_n = 2n$ ,  $n \in \mathbb{Z}$ , are contained in the same set of eigenstates with the exception of the three non-physical states  $A^-\widetilde{\psi_0^-}$ ,  $\widetilde{\Psi_0} = \left( \frac{1}{\psi_2} \right)$ , and  $A^-\widetilde{\psi_3^-}$  of the eigenvalues  $E = 4$ ,  $E = 0$  and  $E = -2$ , respectively. These eigenvalues coincide with the set of zeros of the polynomial  $\Phi(\check{H} + 2)$  that appears in the second relation in (4.7). The preimages of the indicated states are the states  $\chi_a^-$ ,  $a = \alpha, \beta, \gamma$ , having the structure

$$\chi_a^-(x) = \frac{1}{\psi_2^-(x)} \int^x \psi_0(\xi) \psi_2^-(\xi) \left( \int^\xi \psi_0^-(\eta) \rho_a^-(\eta) d\eta \right) d\xi. \quad (4.14)$$

Here  $\rho_\alpha^- = \widetilde{\psi_0^-}$ ,  $\rho_\beta^- = \Omega_{\psi_2^-}$ ,  $\rho_\gamma^- = \widetilde{\psi_3^-}$ , and  $\mathcal{A}^-\chi_\alpha^- = A^-\widetilde{\psi_0^-}$ ,  $\mathcal{A}^-\chi_\beta^- = \widetilde{\Psi_0}$ ,  $\mathcal{A}^-\chi_\gamma^- = A^-\widetilde{\psi_3^-}$ . The states  $\chi_a^-$  are not eigenstates of  $\check{H}$  but satisfy relations

$$\check{H}(\check{H} - 6)\chi_\alpha^- = A^-\psi_0, \quad \check{H}(\check{H} - 2)(\check{H} - 6)\chi_\beta^- = A^-\psi_1^-, \quad \check{H}(\check{H} - 6)\chi_\gamma^- = \Psi_0. \quad (4.15)$$

Figure 3: Discrete flows of the ladder operators of the REQHO. Operator  $\mathcal{A}^-$  acts left and up, and  $\mathcal{A}^+$  acts right and up.

This implies that the following polynomials in the Hamiltonian  $\check{H}$  annihilate the states  $\chi_a^-$ :

$$\check{H}(\check{H} - 6)^2 \chi_\alpha^- = 0, \quad \check{H}(\check{H} - 2)^2(\check{H} - 6) \chi_\beta^- = 0, \quad \check{H}^2(\check{H} - 6) \chi_\gamma^- = 0. \quad (4.16)$$

In correspondence with (4.16), that generalizes relations (2.9), we call the states  $\chi_a^-$  the generalized Jordan states of the REQHO since they are destroyed by the polynomials in  $\check{H}$  with different roots. Note also that

$$(\mathcal{A}^-)^3 \chi_\alpha^- = \Psi_0 \Rightarrow \chi_\alpha^- \in \ker(\mathcal{A}^-)^4, \quad (4.17)$$

whereas  $\chi_\beta^-$  and  $\chi_\gamma^-$  are not annihilated by any degree of the ladder operator  $\mathcal{A}^-$  and in this aspect they are similar to Jordan state  $\chi_2^-$  in the QHO system, see Eq. (6.6).

The kernel of the raising ladder operator is

$$\ker \mathcal{A}^+ = \text{span} \{A^- \psi_3^-, \Psi_0, A^- \psi_0^-\}. \quad (4.18)$$

The action of  $\mathcal{A}^+$  is illustrated by the same Figure 3. The corresponding shown there generalized Jordan states  $\chi_a^+$ ,  $a = \alpha, \beta, \gamma$ , are given by relations similar to (4.14),

$$\chi_a^+(x) = \frac{1}{\psi_2^-(x)} \int^x \psi_0^-(\xi) \psi_2^-(\xi) \left( \int^\xi \psi_0(\eta) \rho_a^+(\eta) d\eta \right) d\xi, \quad (4.19)$$

where  $\rho_\alpha^+ = \Omega_{\psi_2^-}$ ,  $\rho_\beta^+ = \widetilde{\psi_1^-}$ ,  $\rho_\gamma^+ = \widetilde{\psi_0}$ , and  $\mathcal{A}^+ \chi_\alpha^+ = \widetilde{\Psi_0}$ ,  $\mathcal{A}^+ \chi_\beta^+ = A^- \widetilde{\psi_1^-}$ ,  $\mathcal{A}^+ \chi_\gamma^+ = A^- \widetilde{\psi_0}$ . The non-physical eigenstates  $\widetilde{\Psi_0}$ ,  $A^- \widetilde{\psi_1^-}$  and  $A^- \widetilde{\psi_0}$  of  $\check{H}$  appearing here have eigenvalues  $E = 0$ ,  $E = 2$ ,  $E = 6$ , respectively, which correspond to zeros of the polynomial  $\Phi(\check{H})$  in (4.7). The states  $\chi_a^+$  satisfy relations

$$\check{H}(\check{H} + 2)(\check{H} - 4) \chi_\alpha^+ = A^- \psi_3^-, \quad \check{H}(\check{H} - 4) \chi_\beta^+ = \Psi_0, \quad \check{H}(\check{H} - 4) \chi_\gamma^+ = A^- \psi_0^-. \quad (4.20)$$

As a consequence,

$$\check{H}(\check{H} + 2)^2(\check{H} - 4) \chi_\alpha^+ = 0, \quad \check{H}^2(\check{H} - 4) \chi_\beta^+ = 0, \quad \check{H}(\check{H} - 4)^2 \chi_\gamma^+ = 0. \quad (4.21)$$

Note that we have here

$$(\mathcal{A}^+)^3 \chi_\alpha^+ = A^- \psi_0^- \Rightarrow \chi_\alpha^+ \in \ker(\mathcal{A}^+)^4, \quad (4.22)$$

cf. (4.17). The notations for the generalized Jordan states  $\chi_a^\pm$  are chosen so that the ordering in the lower index  $a = \alpha, \beta, \gamma$  in wave functions  $\chi_a^\pm$  corresponds to the ordering in energies of the associated non-physical eigenstates  $\widetilde{\Psi}_0$ ,  $A^-\widetilde{\psi}_1^-$  and  $A^-\widetilde{\psi}_0$ . Generalized Jordan state  $\chi_\alpha^-$  is characterized by the property (4.17) to be similar to the property (4.22) for  $\chi_\alpha^+$ . Under subsequent application of the ladder operator  $\mathcal{A}^+$  to the state  $\chi_\beta^+$  and of the operator  $\mathcal{A}^-$  to  $\chi_\beta^-$ , these states are lifted up to the highest horizontal level shown in Figure 3 to which physical eigenstates do belong, while the generalized Jordan states  $\chi_\gamma^+$  and  $\chi_\gamma^-$  are lifted up by analogous action of the corresponding ladder operator to the lower horizontal level where only non-physical eigenstates of  $\check{H}$  do appear. As in the case of the QHO system, one can proceed and construct iteratively the net of the related generalized Jordan states by finding the pre-images and images of the six basic generalized Jordan states  $\chi_a^\pm$ , and of the generated in such a way new states under the sequential action of the ladder operators  $\mathcal{A}^\pm$ .

A complete isolation of the ground-state  $\Psi_0$  from other normalizable eigenstates  $\Psi_n$  with  $n = 1, 2, \dots$ , reflects here the fact that two irreducible representations of the polynomially deformed superconformal algebra  $\mathfrak{osp}(1|2)$  are realized on the physical bound states of the REQHO system. The operators  $\check{\mathcal{L}}_\pm = \frac{1}{4}\mathcal{A}^\pm$  can be identified as the odd generators of the superalgebra,  $\{\mathcal{R}, \check{\mathcal{L}}_\pm\} = 0$ , while  $\check{J}_0 = \frac{1}{4}\check{H}$  and  $\check{J}_\pm = \frac{1}{4}\mathcal{A}^{\pm 2}$  are its even generators,  $[\mathcal{R}, \check{J}_0] = [\mathcal{R}, \check{J}_\pm] = 0$ . Here, as in the case of the QHO, the operator  $\mathcal{R} = (-1)^{N/2}$  with  $N = a^+a^-$  is the  $\mathbb{Z}_2$ -grading operator,  $\mathcal{R}^2 = 1$ . The nontrivial commutation and anti-commutation relations of the deformed  $\mathfrak{osp}(1|2)$  superalgebra of the REQHO can be found with the help of relations (4.5)–(4.10). They can be presented in the form

$$\{\check{\mathcal{L}}_+, \check{\mathcal{L}}_-\} = \frac{1}{2}\mathcal{C}_{\mathcal{L}\mathcal{L}}(\check{J}_0)\check{J}_0, \quad \{\check{\mathcal{L}}_+, \check{\mathcal{L}}_+\} = \frac{1}{2}\check{J}_+, \quad \{\check{\mathcal{L}}_-, \check{\mathcal{L}}_-\} = \frac{1}{2}\check{J}_-, \quad (4.23)$$

$$[\check{J}_0, \check{\mathcal{L}}_\pm] = \pm \frac{1}{2}\check{\mathcal{L}}_\pm, \quad [\check{J}_+, \check{\mathcal{L}}_-] = -\mathcal{C}_{J\mathcal{L}}(\check{J}_0)\check{\mathcal{L}}_+, \quad [\check{J}_-, \check{\mathcal{L}}_+] = \check{\mathcal{L}}_-\mathcal{C}_{J\mathcal{L}}(\check{J}_0), \quad (4.24)$$

$$[\check{J}_0, \check{J}_\pm] = \pm \check{J}_\pm, \quad [\check{J}_+, \check{J}_-] = -2\mathcal{C}_{JJ}(\check{J}_0)\check{J}_0. \quad (4.25)$$

The operator-valued coefficients

$$\begin{aligned} \mathcal{C}_{\mathcal{L}\mathcal{L}}(\check{J}_0) &= 2 \left( 8\check{J}_0^2 - 10\check{J}_0 + 1 \right), & \mathcal{C}_{J\mathcal{L}}(\check{J}_0) &= 16 \left( \check{J}_0 - 1 \right) \left( 3\check{J}_0 - 1 \right), \\ \mathcal{C}_{JJ}(\check{J}_0) &= 16 \left( 2\check{J}_0 - 1 \right) \left( \check{J}_0 - 1 \right) \left( 24\check{J}_0^2 - 14\check{J}_0 + 7 \right) \end{aligned}$$

appear here instead of the unit coefficients in the  $\mathfrak{osp}(1|2)$  superalgebra (3.5), (3.6) and (3.7) of the QHO. The ground-state  $\Psi_0$  is annihilated by all the generators of the superalgebra and carries its trivial one-dimensional representation. On the higher bound states  $\Psi_n$ ,  $n = 1, 2, \dots$ , infinite-dimensional irreducible representation of the superalgebra is realized. The structure with two irreducible representations is reflected coherently in the discrete flows of the ladder operators depicted on Figure 3.

In conclusion of this section we note that the case of the deformed  $\mathfrak{osp}(1|2)$  superalgebra of the REQHO as well as the  $\mathfrak{osp}(1|2)$  Lie superalgebra of the QHO system can be considered as particular cases of the algebra generated by three elements  $h$ ,  $\alpha^+$  and  $\alpha^-$  subject to the relations

$$[h, \alpha^\pm] = \pm 2\alpha^\pm, \quad \{\alpha^+, \alpha^-\} = F(h) + F(h+2), \quad (4.26)$$

where  $F(h)$  is some polynomial [37]. Such an algebra is characterized by the central element

$$\Xi = \alpha^{+2}\alpha^{-2} + \alpha^+\alpha^- (F(h) - F(h-2)) - (F(h))^2. \quad (4.27)$$

In the case of the QHO we have a correspondence  $\alpha^\pm = a^\pm$ ,  $h = N + 1$  and  $F(h) = N$ . The quadratic Casimir (3.9) of the Lie superalgebra  $\mathfrak{osp}(1|2)$  generated by the rescaled operators  $\alpha^\pm$ ,  $\alpha^{\pm 2}$  and  $h$  is nothing else as the rescaled and shifted for additive constant central element  $\Xi$ ,  $\mathcal{C}_{\mathfrak{osp}(1|2)} = \frac{1}{16}(\Xi - 1)$ . For the REQHO system operators  $\alpha^\pm$  correspond to the ladder operators  $\mathcal{A}^\pm$ , and we have  $h = \check{H}$ ,  $F(h) = \Phi(\check{H})$  with  $\Phi(\check{H})$  defined in (4.7). The superalgebra (4.23)–(4.25) in this case can be considered as a polynomial deformation of the  $\mathfrak{osp}(1|2)$  superalgebra. Using relations (4.7) and (4.10), one can easily check that the central element  $\Xi$  reduces here identically to zero.

## 5 Conclusion and outlook

To conclude, we list some problems to be interesting for further investigation.

We have constructed ladder operators for the simplest version of the REQHO system by the Darboux-dressing of creation and annihilation operators of the QHO. This was done by means of the first order differential operators  $A^-$  and  $A^+$  which intertwine the REQHO and QHO Hamiltonians and factorize both of them. The applied procedure here is analogous to the procedure by which nontrivial Lax-Novikov integrals for reflectionless quantum systems are constructed by the Darboux-dressing of the free particle's momentum operator [48]. But the same REQHO system can also be constructed by means of the Darboux-Crum-Krein-Adler procedure based on the usage of several eigenstates of the QHO. In such a case the intertwiners will be higher order differential operators. One can expect that the existence of different Darboux and Darboux-Crum-Krein-Adler transformations should reveal some new interesting aspects in the construction of the ladder operators for the REQHO and related dynamical symmetries (spectrum generating algebras).

There exist other rational extensions of the QHO system. First, the analogs of the REQHO considered here can be generated by taking non-physical nodeless eigenstate  $\psi_{2n}^-$  with  $n > 1$  as a function  $\psi_*$  to generate Darboux transformations. The ladder operators for such systems can be constructed in a similar way, by the Darboux-dressing of the ladder operators of the QHO. We can generate also then a corresponding polynomially deformed bosonized  $\mathfrak{osp}(1|2)$  superalgebra, whose trivial and infinite-dimensional representations will be realized on physical states of the corresponding rationally extended quantum harmonic oscillator. It is interesting if there will be any essential difference in the structure of the discrete flows generated by the ladder operators in such systems in comparison with the REQHO system considered here. The construction of the ladder operators by taking into account the existence of different Darboux-Crum-Krein-Adler transformations to generate such systems should also reveal a dependence on the order of the polynomial that presents in the structure of the generating function  $\psi_{2n}^-(x)$  and on a size of the gap between the isolated ground-state and the infinite tower of equidistant bound states.

A more complicated and a more rich picture from the point of view of the ladder operators and related symmetries can be expected in rationally extended quantum harmonic oscillator systems with number  $l > 1$  of isolated bound states in the spectrum. There, a priori two essentially different cases should be distinguished. One case is when  $l > 1$  bound states will be separated from the infinite tower of equidistant bound states without any additional gaps between those  $l$  states. Another, more general case is when isolated states include some additional gaps between themselves.

It is known that Jordan states appear in confluent Darboux-Crum transformations [44]. They, particularly, were employed recently for the design of the PT-symmetric optical systems with invisible periodicity defects as well as completely invisible reflectionless PT-symmetric systems [43]. It would be interesting to look for possible physical applications of the generalized Jordan states considered here.

The considered REQHO system as well as its generalizations seem also to be interesting from the point of view of possible physical applications since unlike other known deformations of the QHO, e.g. related to the minimal length uncertainty relation [49, 50], they provide a very specific change of the spectrum. Namely, they add effectively a finite number of bound states in the lower part of the QHO spectrum, separated by an additional (*adjustable*) gap, without disturbing the equidistant character of the rest of the infinite tower of the discrete levels. In this aspect they are very similar, as it has been noted above in another but related context, to the quantum reflectionless systems which add a finite number of discrete bound states into the spectrum of the free particle. Such reflectionless systems are directly related to the soliton solutions to the Korteweg-de Vries and modified Korteweg-de Vries equations, and find a lot of interesting applications in very diverse areas of physics including QCD, cosmology, solid states physics, the physics of polymers, plasma physics, and quantum optics, just to mention a few <sup>2</sup>. Further results related to the ladder operators in rationally extended harmonic oscillator systems, which exploit the indicated similarity, will be presented elsewhere [52].

## 6 Appendix: Discrete chains of the states of the QHO

We describe here the action of the ladder operators  $a^+$  and  $a^-$  on non-physical eigenstates  $\widetilde{\psi}_n$  and  $\widetilde{\psi}_n^-$  of the QHO and the construction of the associated Jordan and generalized Jordan states.

Making use of the identities  $H'_n = 2nH_{n-1}$  and  $H_n = 2xH_{n-1} - H'_{n-1}$  for Hermite polynomials, we obtain the relations

$$\int^x \frac{e^{\xi^2}}{H_n^2(\xi)} d\xi = -\frac{1}{2n} \int^x \frac{e^{\xi^2}}{H_{n-1}(\xi)} d\left(\frac{1}{H_n(\xi)}\right) = -\frac{e^{x^2}}{2nH_nH_{n-1}} + \frac{1}{2n} \int^x \frac{e^{\xi^2}}{H_{n-1}^2} d\xi, \quad (6.1)$$

from where we find that

$$a^- \widetilde{\psi}_n = \widetilde{\psi}_{n-1}, \quad n = 1, 2, \dots \quad (6.2)$$

Application to both sides of this equality of the operator  $a^+$  gives

$$a^+ \widetilde{\psi}_n = \widetilde{\psi}_{n+1}, \quad n = 0, 1, \dots \quad (6.3)$$

Changing  $x \rightarrow ix$  in (6.2) and (6.3), and taking into account that  $a^- \rightarrow ia^+$ , we also obtain

$$a^+ \widetilde{\psi}_n^- = \widetilde{\psi}_{n-1}^-, \quad n = 1, 2, \dots, \quad a^- \widetilde{\psi}_n^- = \widetilde{\psi}_{n+1}^-, \quad n = 0, 1, \dots \quad (6.4)$$

In correspondence with (2.5) and (2.6),

$$a^- \widetilde{\psi}_0 = \frac{1}{\psi_0} = \psi_0^-, \quad a^+ \widetilde{\psi}_0^- = \psi_0. \quad (6.5)$$

---

<sup>2</sup>See, e.g., [15, 48, 51] and references therein.

We also have

$$\chi_2^-(x) = \psi_0(x) \int^x \psi_0^-(\xi) \widetilde{\psi_0^-}(\xi) d\xi, \quad a^- \chi_2^-(x) = \widetilde{\psi_0^-} \equiv \chi_1^+. \quad (6.6)$$

This is a Jordan state which obeys the relations  $(H-1)\chi_2^- = \psi_0$ ,  $(H-1)^2\chi_2^- = 0$ , where  $H = a^+a^- + 1$ . Analogously,

$$\chi_2^+(x) = \frac{1}{\psi_0} \int^x \psi_0(\xi) \widetilde{\psi_0}(\xi) d\xi, \quad a^+ \chi_2^+ = \widetilde{\psi_0} \equiv \chi_1^-, \quad (6.7)$$

and  $(H+1)\chi_2^+ = \psi_0^-$ ,  $(H+1)^2\chi_2^+ = 0$ .

Proceeding from the states  $\chi_2^+$  and  $\chi_2^-$ , one can construct an infinite net of related to them Jordan and generalized Jordan states. First, as analogs of  $\Omega_n$  and  $\check{\Omega}_n$  defined in (2.10) we have the states  $\chi_n^-$  and  $\chi_n^+$ ,

$$\chi_n^-(x) = \psi_0(x) \int^x \psi_0^-(\xi) \chi_{n-1}^+(\xi) d\xi, \quad \chi_n^+(x) = \psi_0^-(x) \int^x \psi_0(\xi) \chi_{n-1}^-(\xi) d\xi, \quad (6.8)$$

where the case  $n=1$  is also included by assuming  $\chi_0^- \equiv \psi_0$  and  $\chi_0^+ \equiv \psi_0^-$ . These are the higher order Jordan states (2.10) generated on the basis of  $\psi_* = \psi_0$ . They satisfy relations  $a^- \chi_n^- = \chi_{n-1}^+$ ,  $a^+ \chi_n^+ = \chi_{n-1}^-$ , and, consequently,  $a^-(a^+a^-)^n \chi_{2n}^- = 0$ ,  $a^+(a^-a^+)^n \chi_{2n}^+ = 0$ . Therefore,  $(H-1)^{n+1} \chi_k^- = 0$  and  $(H+1)^{n+1} \chi_k^+ = 0$  for  $k = 2n, 2n+1$ .

One can define  $\sigma_n^- = a^+ \chi_n^-$ ,  $\sigma_n^+ = a^- \chi_n^+$ ,  $n = 2, \dots$ . These are Jordan states obeying the relations  $(H-3)^n \sigma_{2n}^- = \psi_1$ ,  $(H-3)^n \sigma_{2n+1}^- = \widetilde{\psi_1}$ ,  $(H+3)^n \sigma_{2n}^+ = \psi_1^-$ ,  $(H+3)^n \sigma_{2n+1}^+ = \widetilde{\psi_1^-}$ , and, therefore,  $(H-3)^{n+1} \sigma_k^- = 0$ ,  $(H+3)^{n+1} \sigma_k^+ = 0$  for  $k = 2n, 2n+1$ .

In the same vein the family of Jordan states  $\tau_n^- = a^+ \sigma_n^-$  and  $\tau_n^+ = a^- \sigma_n^+$ ,  $n = 2, \dots$ , can be defined. They satisfy the relations  $(H-5)^n \tau_{2n}^- = \psi_2$ ,  $(H-5)^n \tau_{2n+1}^- = \widetilde{\psi_2}$ ,  $(H+5)^n \tau_{2n}^+ = \psi_2^-$ ,  $(H+5)^n \tau_{2n+1}^+ = \widetilde{\psi_2^-}$ , and  $(H-5)^{n+1} \tau_k^- = 0$ ,  $(H+5)^{n+1} \tau_k^+ = 0$  for  $k = 2n, 2n+1$ . These discrete flows can be further continued ‘horizontally’.

On the other hand, the states defined via  $\gamma_n^- = a^+ \sigma_n^-$ ,  $\gamma_n^+ = a^- \sigma_n^+$ ,  $n = 2, \dots$ , are reduced to linear combinations of the already introduced Jordan states. Namely,  $\gamma_n^-$  is a linear combination of  $\chi_n^-$  and  $\chi_{n-2}^-$ , and  $\gamma_n^+$  is a linear combination of  $\chi_n^+$  and  $\chi_{n-2}^+$ .

Consider the states  $\lambda_n^\pm$  given by means of relations  $a^- \lambda_n^- = \chi_{n-1}^-$ ,  $a^+ \lambda_n^+ = \chi_{n-1}^+$ ,  $n = 3, \dots$ . The states  $\lambda_n^-$  can be presented in the form similar to that for  $\chi_n^-$  in (6.8) but with  $\chi_{n-1}^+$  in the integrand changed for  $\chi_{n-1}^-$ . Analogously,  $\lambda_n^+$  are presented similarly to  $\chi_n^+$  in (6.8) with  $\chi_{n-1}^-$  in the integrand changed for  $\chi_{n-1}^+$ . For these states we have relations  $(a^+a^-)^n a^- \lambda_{2n}^- = 0$ ,  $(a^-a^+)^n a^+ \lambda_{2n}^+ = 0$ ,  $a^-(a^+a^-)^n a^- \lambda_{2n+1}^- = 0$ ,  $a^+(a^-a^+)^n a^+ \lambda_{2n+1}^+ = 0$ . As a consequence,  $(H-1)\lambda_n^- = \chi_{n-2}^-$ ,  $(H+1)\lambda_n^+ = \chi_{n-2}^+$ . Therefore, these are generalized Jordan states which obey the relations  $(H-1)(H-3)^n \lambda_k^- = 0$ ,  $(H+1)(H+3)^n \lambda_k^+ = 0$  with  $k = 2n, 2n-1$ .

Similarly, generalized Jordan states  $\mu_n^\pm(x)$  can be defined proceeding from the states  $\lambda_n^\pm$  via the relations  $a^+ \mu_n^- = \lambda_{n+1}^-$ ,  $a^- \mu_n^+ = \lambda_{n+1}^+$ ,  $n = 2, \dots$ . Then

$$\mu_n^-(x) = \psi_0^-(x) \int^x \psi_0(\xi) \lambda_{n+1}^-(\xi) d\xi, \quad \mu_n^+(x) = \psi_0(x) \int^x \psi_0^-(\xi) \lambda_{n+1}^+(\xi) d\xi. \quad (6.9)$$

For these states we have  $\chi_n^- = (H+1)\mu_n^-$ ,  $\chi_n^+ = (H-1)\mu_n^+$ . They are generalized Jordan states obeying the relations  $(H+1)(H-1)^{n+1} \mu_k^- = 0$ ,  $(H-1)(H+1)^{n+1} \mu_k^+ = 0$  with  $k = 2n, 2n+1$ .

The described procedure of the construction of the Jordan and generalized Jordan states can be continued further in the obvious way. The discrete flows corresponding to the action of the ladder operators on the physical and associated non-physical eigenstates of the QHO Hamiltonian and associated Jordan and generalized Jordan states are illustrated by Figure 2.
